SUMMARY

Finite element programs such as PAFEC often produce vast quantities of data which need to be processed. For analysis purposes only certain information is required and the rest is often discarded. However, the massive amounts of output generated sometimes makes it difficult to locate the relevant information. This report provides a brief outline of a suite of programs which have been developed for use with PAFEC to enable easier processing of the relevant data.

1. INTRODUCTION

Finite element programs generate vast amounts of numerical data. This set of data has to be processed by the user to obtain the required information about a particular numerical model or process results, e.g. find crack tip nodes or stresses around a crack tip. The purpose of the suite of programs presented in this report is to simplify the processing of this information.

The PAFEC finite element package provides the programmer with a suite of subroutines that allow access to the data held in the PAFEC database. Using these subroutines independent programs can be written to manipulate sections of the database in the required way.

The suite of programs presented in this report are divided into two distinct sections. The first section discusses those programs which enable the user to access and modify the database. With some programs the modified information can be stored into the database. The second section deals with the post processing of results. In some cases the output from the first section can be used as the input to the post processing programs.

The purpose of this report is to provide a brief outline of each of the application programs currently available. The execution of the programs is simplified by the fact that they are interactive i.e., the programs prompt the user for the required information. There exists a fairly high degree of error trapping which allows recovery if the incorrect data are entered. However there is always the contingency that the user will have to start from scratch.

2. ACCESSING PAFEC PROGRAMS

Executable versions of the application programs can be accessed by users on the LINN computer at the Aeronautical Research Laboratories (ARL). The path name of the area is as follows:

/Applications/Te/packages/pafec/pafec

To access these files aliases are created in the users command directory pointing to the particular file on the PAFEC area. It is envisaged that with future levels of PAFEC this will be changed and will require the user to modify their command search rule to access the PAFEC commands directory. At present a shellfile (i.e., an executable command language file) on the PAFEC area, which is called PAFEC-SET-UP, automatically assigns all the relevant alias for the user. It also sets up the the users command directory so that they can execute PAFEC.

3. PROGRAM DESCRIPTIONS

3.1 PROGRAMS FOR MODEL MANIPULATION

3.1.1 Program name: NODEFIND

Description: The NODEFIND program is used to extract node numbers and their co-ordinates. The menu provided allows the easy selection of a multitude of search patterns. The tolerance on searching the nodal co-ordinates can be changed to adjust for numerical drift in the coordinate value. Nodes can be read from an external file if the procedure has to be repeated many times.

Output file name: [Jobname] NODES

Output description: Pafec job name
Tolerance used
Description of option chosen
Node, X, Y, Z, Radius, Theta (relative to input node)
Data.

3.1.2 Program name:**PAFGRFIND****Description:**

Element data in a finite element program is made up of group numbers, property numbers and nodal topology. PAFGRFIND is used to extract this set of data. There are two options, one which allows the input of a node number and the other which requires the element number.

Output file name:

[Jobname].GRFIND

Output description:

Pafec job name
 Option description
 Node, element, group, element type, property numbers
 Data
 or
 Element, group, property numbers and topology
 Data

3.1.3 Program name:**PAFINFO****Description:**

PAFEC stores information about the structure in an array called IBASE. This program displays the information outlined in the output description section and can be very useful in extracting information pertaining to a particular backing store file.

Output file name:

[Jobname].INFO

Output description:

Current phase indicator
 Nodal information
 Job tolerance
 Element information
 Number of degrees of freedom
 Dimension of stiffness matrix
 Plane stress or plane strain
 Error and warning count for the current phase

3.1.4 Program name:**PAFTRIM****Description:**

This program allows the extraction of elements with their corresponding nodes from a PAFEC backing store. The nodes extracted can be renumbered from 1 if required. PAFTTRIM can be used to extract a substructure from a much larger model. It can also be used to check if elements have collapsed. The output file is written as a PAFEC data file with only nodal and elemental data.

Output file name:

[Jobname].TRIM

Output description:

Pafec phase 1 control module
 Nodes module header
 Data
 Elements module header
 Data
 END OF DATA card

3.4.5 Program name	PACENTROID
Description	This program calculates the centroid of all elements in the structure and with the provided search information it outputs the element numbers from 1. This is then used in conjunction with PAMGRSLT (see 3.4.6) to set the group number of the elements to a group number not currently used. Then when run in PIG (Pafe Integrated Graphics) only the selected group can be drawn, thereby allowing slices of the structure to be drawn.
Output file name	[Jobname].CENT
Output description	Element X, Y, Z centroid coordinates. Below this is a list of elements for PAMGRSLT input.
	Data
	List of elements for PAMGRSLT input.
	Data
3.4.6 Program name	PAMGRSLT
Description	This program changes the group number of the elements listed in an input file to the required group number. The elements that are to have their group numbers changed must exist in a column file so that the program can access them. PAMGRSLT can be used to change element group numbers in the background routine and the job can be restarted with the modified group numbers used in conjunction with an existing PAIEC input module. This is useful if the numerical model was saved before generated.
Output file name	[Jobname].BS (MODIFIED)
Output description	None
	WARNING
	It should be noted that this program modifies the background file and might, in some instances, not allow the user to restart a problem. Therefore great care must be taken when using this program.
3.4.7 Program name	ENQIBASE
Description	When writing PAIEC code it is very useful to know the values of certain PAIEC control and structural constants. This program allows the programmer to examine the value of any IBASE number. IBASE is the PAIEC array that holds these control and structural constants.
Output file name	None (Output is to the terminal)
Output description	IBASE number and value
3.4.8 Program name	GAPS
Description	Locating the GAPS and BACKUP modules in other dimensional problems and computing the total time consumed. The GAPS program will calculate all the relevant times and then the check times for each two-dimensional problem in turn. The check function is to ensure that the total time is not exceeded if required. The GAPS program is used for one- and two-dimensional problems.

Output file names	[Jobname] GAPS [Jobname] GAPINO
Output description	Gaps module header Data Crack tip module header Data Paired gap nodes NODL, X, Y, Z coordinates, Ratch, Theta Data
[Jobname] [Jobname] [Jobname] [Jobname]	GAPINO

3.4.9 Program name:**SCAL****Description**

In some problems, especially with composite materials, where the aspect ratio of elements is sometimes very large, it is where the structure in PIC8 is difficult. SCAL allows the user to scale up or down the X, Y or Z coordinates by a factor thereby enabling a clearer view of the structure.

Output file name:

[Jobname] BS (MODIFIED)

Output description

None

WARNING

It should be noted that this program modifies the binary state file and might not allow a successful restart of a problem. SCAL can be used in reverse to return the backing state coordinates to their original values before being modified.

3.4.10 Program name:**DEFLAMINATION****Description**

This program will create one complete PAIIC layer with a hole and a circular delamination at the specified layer in the composite. The output file has a complete list and description of all the parameters used. The program will need to be implemented if these parameters are chosen. DEFLAMINATION can create a structural model with or without the delamination, and with or without a patch on the top surface.

Requested at run time:

See created output file for full description of inputs and the PAIIC modules to be used.

3.4.11 Program name:**NODEEQIV****Description**

Sometimes two data files with the same structure but different methods need to be compared. The methods of the structure often cannot be directly compared because NODEEQIV compares the crack tip locations. It is for this reason that an equivalent coordinate system is used. This is done by reading from a dummy file containing a point in each coordinate system.

Output file name:

[Jobname] EQIV.out (TCL)

Output description

Two files are created, one in X, Y, Z coordinate Data

3.2 POST PROCESSING PROGRAMS

3.2.1 Program name

Description

PAI-STRESS

For large finite element problems, vector quantities of interest may not be generated. PAI-STRESS is designed to reduce the size of output to a manageable quantity. The program provides the ability to extract nodal or elemental averaged or individual stresses. The elemental global stresses are displayed when the average option is selected and the primary stresses are presented when the averaged option is chosen. Output to the terminal is limited, but all information is written to the output file.

PAI-STRESS accesses two files; the first is the *Element Stress* and the second is called the *SS* file. The *Element Stress* file has the ability to check the requested node or element number which exists in the structure and provide the program with the properties of the requested element. The *SS* file provides the stress information and is accessed through a slightly modified PAI-EC routine of the routine R70000 (see PAI-EC Data Preparation User Manual, Level 6.2, section 7.12.5).

Output file name

Jobname_STRESS

Output description

Pafec job name

Option description

Element, node, σ_x , σ_y , σ_z , σ_{xy} , σ_{yz} , σ_{xz}

or

Element, node, σ_1 , σ_2 , σ_3 , α_1 , α_2 , α_3

Note 1

There exists in the PAI-EC code a program bug which causes the stress records to be written to the *SS* file. This bug will be corrected in PAI-EC level 7. Due to this bug PAI-STRESS will sometimes print duplicate information for particular nodes.

Note 2

Initially on using PAI-STRESS it is advised to run simple test output with the output from PAI-STRESS. If no difference occurs then ignore the PAI-STRESS computation as the *SS* file will somehow have become corrupt.

Note 3

PAI-STRESS will only produce stresses for the elements listed in the PAI-EC STRESS ELEMENT module.

3.2.2 Program name

Description

DISPL

The PAI-EC level 7 calculates all the elasto-dynamic displacements for the numerical model. DISPL can be used to extract the nodal displacement required. If more than one load case is present then the program will automatically run this and prompt for the load case required. The program can also be used to check the status of gaps nodes and this comes under the option of nodal pairs differences.

Output file name

Jobname_DISPL

Output description

Pafec job name

Node, Ux, Uy, Uz displacement

or

Node, Ux, Uy, Uz displacement, U1, U2, ..., Un

3.2.3 Program name:**Description:****PLASDISPL**

The displacements for a PAFFC plasticity analysis are just stored for each load increment due to the amount of storage space required. If the displacements are required at each step size of the load increments then modifications are required to the control file and to the PAFFC code. These modifications are difficult to follow and result in the displacements being stored in memory files. After the analysis has been completed, PLASDISPL can then be executed to extract the displacements at any load increment from the [jobname].DISP.

Output file name:

None

Output description:

Node, Ux, Uy, Uz displacements to terminal

Data file changes:

The following lines should be inserted after the PAFFC statement in the control module:

USE PLASJNT

ADD PROG:

```
CALL R09806(MLG,JROW,IP06)
IREC = MLG + 4
OPEN(UNIT=72,FILE='[JOBNAME].DISP',
  FORM='UNFORMATTED',ACCESS='DIRECT',
  RECL=IREC,STATUS='NEW')
END OF ADD PROG
```

PAFFC code changes:

Insert the following lines in routine INCIDIS in PLASJNT.F before the return statement:

IDCHAN = 79

CALL R00401(IDCHAN,INCT,BASE(IP06),IMC2)

3.2.4 Program name:**Description:****PAFSTRAIN**

The program PAFSTRAIN can be used to extract the strain values for nodes and elements in exactly the same manner as PAFSTRESS (see 3.2.4). The program accesses the ET file in which PAFFC has written the strain records. The UT file is only written if the user has requested a nonlinear analysis. This file is usually deleted after completion of the analysis by the PAFFC shell commands. If required by any user then the control module option of SAVE ET,UT,HE should be used in control module.

Output file name:

[Jobname].STRAIN

Output description:

Pafec job name

Option description:

Element or node number

Load case, Group, Element, Node, ...

or

Load case, Node, ..., group, ..., G₁, G₂, G₃**3.2.5 Program name:****Description:****PAFSTRCAL**

Sometimes it is desirable to calculate the strains through certain sections of the structure. PAFSTRCAL will calculate the strains using the following formula:

$$\frac{U_1 - U_2}{\Delta L}$$

where U_1, U_2 are the displacements of the two points in the x or y direction and Δ is the distance between the two points in the x , y or z direction. The program requests the direction of the line and then a node on the line. Only the corner nodes that exist on the line are used in the above formula.

Output file name:	[Jobname] STICAI
Output description:	Data: (X, Y or Z coordinate), (X, Y or Z difference), (U_x, U_y, U_z) , $(U_x, U_y \text{ or } U_z \text{ difference})$
	Printed data:

3.2.6 Program name:

Description:

ENERGY

Failure analysis of composite material may involve the calculation of a number of parameters such as the strain energy density, volume fraction ($\epsilon_{11}, \epsilon_{22}, \epsilon_{33}$) and area fraction. ENERGY uses the backbone store file and the SS file to retrieve the stresses and strains for orthotropic material elements only. To examine a particular point in the structure the node and element number is required. If the element number is given, *energy* the program will provide a list of elements attached to that node number.

Output file name:	[Jobname] ENERGY
Output description:	Printed parameters: Node, Element, $\sigma_{xx}, \sigma_{yy}, \sigma_{zz}, \epsilon_{xx}, \epsilon_{yy}, \epsilon_{zz}$
	Data: Total energy Available energy DV DA1 DA2 DA3 Message depending whether DV, DA1, DV, DA2 or DV, DA3 is the maximum

3.2.7 Program name:

Description:

MODAL

Analyzing a viscoelastic material using the PALEC dynamic analysis, involves determining the modal strain energy for each element and for each mode shape. PALEC produces tables of strain energy, but it is convenient to manipulate these tables in terms of the elements defined as viscoelastic. The MODAL program calculates the strain energy for each element and mode and assumes that the viscoelastic elements are defined as group 1 in the numeric model. The loss factor for the viscoelastic elements is assume to be 1. To be able to use the MODAL, the elemental stiffness file (P1) must not be deleted at the end of the run. To stop the PALEC shell command from deleting this file, the option SAV1=SHELL must be included in the control module.

Output file name:	[Jobname] MODAL
Output description:	Title Element, Mode 1, Mode 2, ..., Mode 10
	Data: Element, Mode 11, Mode 12, ..., etc

Data

Element Matrix for the finite element
Model Strain energy for the finite element
Model Strain energy for the finite element
Load Factor for the finite element
Load Factor for the system

4. DISCUSSION

The suite of programs contained in this report are useful tools in analysing PAFF models. The programs allow repetitive work to be carried out with the minimum effort. They do not take away the need for the user to check information and if doubt occurs then the PAFF output should generally be believed before the output from the particular program. As mentioned earlier, extensive error trapping is performed, but sometimes the path through the programs that the user takes may cause a problem to arise.
